

Appendix: convergence across models, solvers, parameters and seeds (N=16)
col 0: multi-solver comparison (median+IQR band where seeds $\geq$ 5, else individual seeds), dashed = exact energy
cols 1-2: parameter sweep, single classical solver, individual seeds
solver panels use one shared hyperparameter cell per model, not each solver's own tuned config -- some spread
(e.g. VeloxQ and one Metropolis seed settling on a metastable plateau in TFIM 2D) reflects that, not a plotting artifact
